

### **Self-Reflection:**

The Nilgiri Tahr, an endemic species of the southern Western Ghats is endangered due to several factors such as climate change, habitat loss and fragmentation. For the proper protection and conservation of this species, we need to know the best niche models for it and this paper helps us to understand these models as well as predicts the future of the Nilgiri Tahr if the current scenario continues to worsen. This was achieved with help of technological tools like ArcGIS, MaxEnt, SDMToolBox and R, thus highlighting the importance of interdependence of technology with ecosystem of a species and how it not only helps to understand the threats faced but also helps in the proper conservation planning when used properly.

I understood the importance of Ecological Niche Models or ENMs which helped us understand the ideal niche model on the basis of the five bioclimatic factors and the future of the Nilgiri Tahr under different scenarios and decades thus acting as a significant ecological tool that is used for conservation and reserve planning which would significantly help this endangered species.
